Inform yourself to make a better treatment plan.

All breast cancer is not the same. Each woman is unique. You have treatment choices. In the coming weeks, your doctor will work with you to create a treatment plan based on the distinct biology of your cancer.

Each breast cancer treatment requires a specialized approach.

Genomic tests can provide a greater understanding of your cancer. A genomic test examines breast cancer at a molecular level and can help predict how it will react to certain treatments.

Better treatment decisions occur when you and your doctor are completely informed.

Decide your path with confidence. The Oncotype DX® Breast Cancer Assay is a genomic test shown to predict if chemotherapy will be beneficial for women with early-stage cancer, and is also available to help determine the risk of recurrence for women with ductal carcinoma in situ (DCIS). The test is done on tissue collected during a biopsy or surgery, and requires no additional medical procedure.
